# Snake Table: A Dynamic Pivot Table for Streams of k-NN Searches

---

Juan Manuel Barrios\*, **Benjamin Bustos\***, Tomas Skopal^

\* KDW+PRISMA, University of Chile

^ SIRET, Charles University in Prague

---

# Motivation

- Video copy detection
- Observations
  - Consecutive queries are similar
  - Long query streams
  - Cheap distance function
- Is it possible to take advantage of the properties of query streams for improving the efficiency of k-NN?

---

# Outline

- Streams of k-NN searches
- D-file and D-cache
- Snake Table and snake distribution
- Experimental evaluation
- Conclusions and future work

---

# Streams of k-NN searches

- Sequence of queries
  - May have properties that can be exploited
- Example: queries from videos
  - Queries are frames (images) from the video
  - Usually 25 frames per second
  - Consecutive frames from the same shot are similar
    - Previous query could be used as an effective pivot!

---

# Related work: D-file and D-cache

- D-file: just the original database using sequential scan, BUT
- it uses D-cache
  - a memory-resident structure that maintains the distances computed during previous queries
  - **provides lower-bounds (pivot based)** of requested distances that can be used to filter some of the database objects when querying
  - **$O(1)$**  complexity for a lower bound retrieval
- **no preprocessing of database**

---

# Related work: D-file and D-cache

- D-file works well if distance computation is “expensive”
- Otherwise, the overhead of D-cache may be too high, even if it discards many distance computations
  - Hash function computation
  - Distance insertion + replacement cost (collision resolution)

---

# Snake Table

- Pivot-based index aimed to:
  - Improve the search time for streams of queries where consecutive query objects are similar
    - We call this “snake distribution”
  - Keep its internal complexity low to be applied in systems that use fast distance functions
    - E.g., CBVCD systems and interactive CBMIR that use global descriptors and Minkowski distances

# Snake distribution

**Fig. 1.** Stream of queries  $Q=\{q_1, \dots, q_{12}\}$  with a snake distribution: most of distances  $d(q_i, q_{i+1})$  are smaller than  $d(x, y)$  for randomly selected pairs  $x, y$  in  $\mathcal{R}$ .

---

# Snake Table

- Life cycle
  - When a new session starts, an empty Snake Table is created
  - When a query  $q$  is received:
    - $k$ -NN is performed
    - Distances computed are stored in the table
    - Result is returned
  - In the following queries
    - Previous query objects are used as pivots
  - When the session ends, table is discarded

# Snake Table

- Data structure
  - Fixed-sized matrix used as a dynamic pivot table ( $p$  pivots)
  - Each cell in the  $j$ -th row contains a pair  $(q, d(q, o_j))$  for some  $q$  (not necessarily in order)
  - At query time
    - Lower bound distance is computed for discarding  $o_j$
    - If object  $o_j$  is not discarded, computed distance is stored in the table

# Snake Table

- Replacement strategies
  - V1: round-robin mode
    - If distance was not computed
      - Cell is left unmodified, but must be checked in further queries before computing lower bound
  - V2: highest distance in the row is replaced
  - V3: “independent” round-robin
    - for each row, every rows compactly stores the last  $p$  evaluated distances
    - Lower bound distance computed from last query and goes backwards

---

# Experimental evaluation

- Dataset
  - MUSCLE-VCD-2007 (Video copy database)
  - Descriptors:
    - Edge Histogram
    - Ordinal Histogram
    - Color Histogram
    - Keyframe
    - Linear combinations of these descriptors
  - Distance: L1 (Manhattan)

---

# Experimental evaluation

- Indexes
  - D-cache
  - LAESA
    - LAESA-R: choose pivots from data set
    - LAESA-Q: choose pivots from queries
    - Pivots chosen using SSS (Sparse Spatial Selection)
  - Snake Table: SnakeV1, SnakeV2, SnakeV3
- All indexes of same size
- $p$  varies between 1 and 20

# Experimental evaluation

	Time	MAP	max	$\mu$	$\sigma$	$\rho$	$H_d$
<b>Group 1</b>							
OM	282 s.	0.125	3285	1489	416	6.4	
KF	304 s.	0.509	24721	7264	2636	3.8	
<b>Group 2</b>							
EH	541 s.	0.639	7996	3198	751	9.1	
CH	501 s.	0.482	6219	3661	970	7.1	
<b>Group 3</b>							
ECK	1258 s.	0.646	0.888	0.416	0.09	11.4	
EK3	2214 s.	0.732	0.870	0.347	0.08	10.2	

Table 1. Effectiveness and efficiency for the base configurations.

# Experimental evaluation

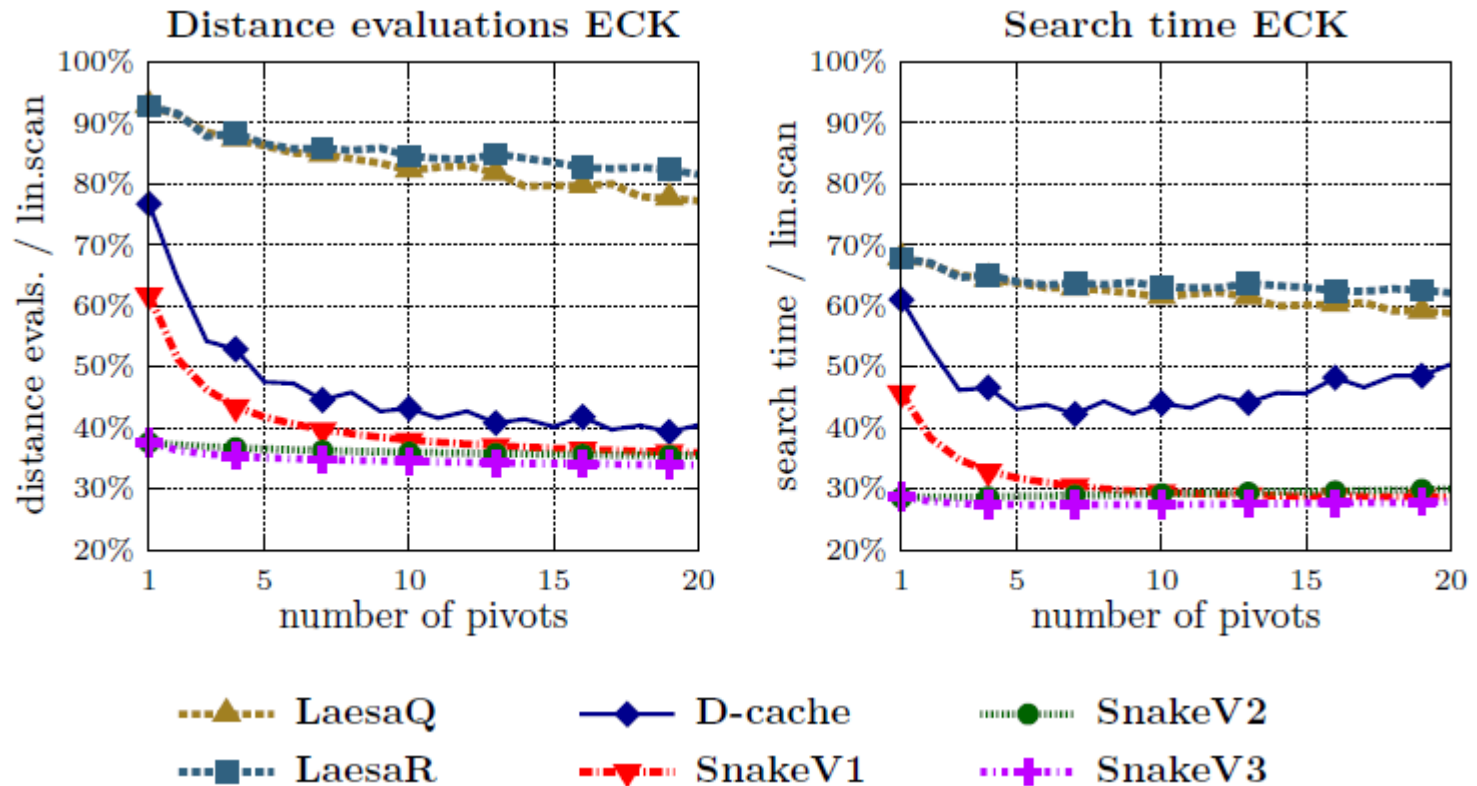

# Experimental evaluation

# Experimental evaluation

---

# Conclusions and future work

- Snake Table achieves high performance with queries that follows a snake distribution
  - This is due to dynamic selection of good pivots
  - It's better to avoid empty or unused cells
- No preprocessing needed
- Better alternative than D-cache in the tested scenarios

---

# Conclusions and future work

- It requires space proportional to the dataset
  - Not memory efficient
- Suitable for medium-sized data sets with long k-NN streams (like in video retrieval)

---

# Conclusions and future work

- Future work:
  - When  $p$  is high, many pivots are close to each other
    - They may become redundant
    - Possible solution: use a mix of static and dynamic pivots
  - Solve parallel queries with Snake Table

---

# D-file – range query

```
set RangeQuery( $Q, r_Q$ ) {
```

```
  for each  $O_i$  in database do
```

```
    compute  $\delta(Q, O_i)$ ;
```

```
    if  $\delta(Q, O_i) \leq r_Q$  then add  $O_i$  to the query result }
```

```
// basic filtering
```

~~sequential search~~ enhanced by D-cache filtering

# Snake distribution

- Formal definition:

**Definition 3** (*Snake Distribution*) Let  $\mathcal{M} = (\mathcal{D}, d)$  be a metric space, let  $\mathcal{R} \subset \mathcal{D}$  be the collection of objects, and let  $\mathcal{Q} \subset \mathcal{D}$  be a set of  $m$  query objects  $\mathcal{Q} = \{q_1, \dots, q_m\}$ . Let  $F$  be the cumulative distribution of  $d(x, y)$  with random pairs  $x, y \in \mathcal{Q} \cup \mathcal{R}$ ,  $p$  be a number between 1 and  $m-1$ , and  $F_{\mathcal{Q}}^p$  be the cumulative distribution of  $d(q_i, q_{i-p}) \forall i \in \{p+1, \dots, m\}$ .  $\mathcal{Q}$  fits a snake distribution of order  $p$  if  $\Delta(F_{\mathcal{Q}}^p, F) > s$ , for some threshold value  $s \in \mathbb{R}^+$ .

# Index-based metric access methods

- All metric access methods (MAM) are **index-based**, i.e., preprocessing of a database is always needed.
- Index construction takes between  $O(n \log n)$  and  $O(n^2)$ .

# Outline

- Pivot-based indexing
- Motivation for index-free similarity search
- D-file (+ D-cache)
- Snake Table
- Final remarks

# Using lower-bound distances for filtering database objects

- cheap determination of **lower-bound distance** of  $\delta(*,*)$

The task: check if  $\mathbf{X}$  is inside query ball

- we know  $\delta(Q,P)$

- we know  $\delta(P,X)$

- we do not know  $\delta(Q,X)$

- we do not have to compute  $\delta(Q,X)$ , because its lower bound  $|\delta(Q,P) - \delta(X,P)|$  is larger than  $r$ , so  $\mathbf{X}$  surely cannot be in the query ball, so  $\mathbf{X}$  is ignored

- this filtering is used in various forms by metric access methods, where  $\mathbf{X}$  stands for a database object and  $\mathbf{P}$  for a pivot object

# Motivation for index-free search

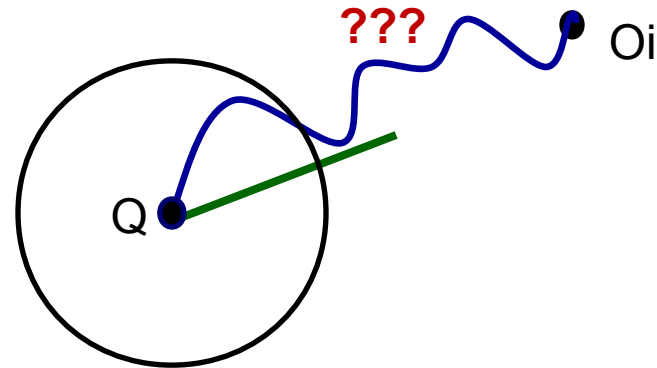

- indexing is not desirable (or even possible) if
  - we have a highly **changeable** database
    - more inserts/deletes/updates than searches, i.e., streaming databases, archives, logs, sensory databases, etc.
  - we perform **isolated** searches
    - a database is created for a few queries and then discarded, i.e., in data mining tasks
  - we switch between distances (**changing similarity**)
    - the distance function is tuned at query time, e.g., weighing of object features is applied dynamically

---

# D-file

- just the original database using sequential scan, BUT
- it uses D-cache
  - a memory-resident structure that maintains the distances computed during previous queries
  - **provides lower-bounds** of requested distances that can be used to filter some of the database objects when querying
  - **O(1)** complexity for a lower bound retrieval
- **no preprocessing of database**

# D-file – range query

```
set RangeQuery( $Q, r_Q$ ) {
```

```
  for each  $O_i$  in database do
```

```
    compute  $\delta(Q, O_i)$ ;
```

```
    if  $\delta(Q, O_i) \leq r_Q$  then add  $O_i$  to the query result }
```

```
// basic filtering
```

~~simple sequential search~~ enhanced by D-cache filtering

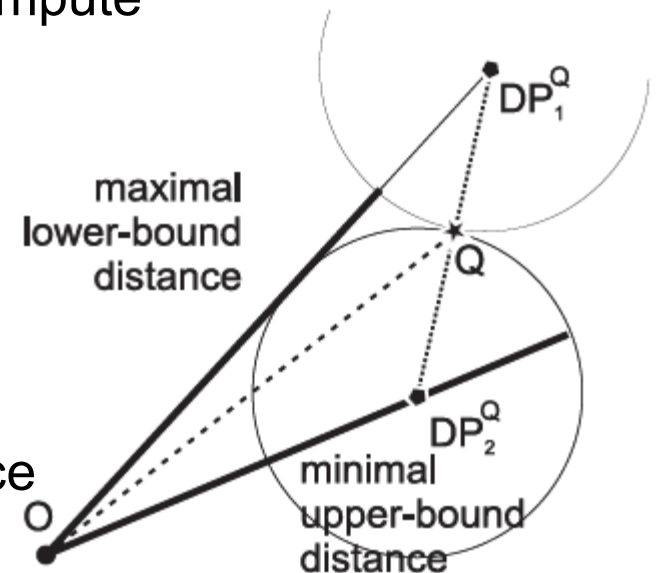

# D-cache

- every time a D-file computes a distance  $\delta(*,*)$ , it is stored into D-cache
- the D-cache could be viewed as a sparse matrix, where queries denote row, database object denote columns, and a cell contains value of  $\delta(Q,O)$

$$D = \begin{matrix} & O_1 & O_2 & O_3 & \dots & O_n \\ Q_1 & & d_{12} & d_{13} & \dots & \\ Q_2 & d_{21} & & & \dots & d_{2n} \\ Q_3 & & & & \dots & \\ \dots & \dots & \dots & \dots & \dots & \dots \\ Q_m & d_{m1} & & d_{m3} & \dots & \end{matrix}$$

# D-cache

- D-cache has two functionalities
  - it allows to retrieve the exact distance  $\delta(Q, O)$ , if it is there
  - the main functionality: it provides *tight lower bound* to  $\delta(Q, O)$
- How to obtain a lower bound?
  - prior to a new query  $Q$ , determine some old queries  $DP_i^Q$  (acting as **dynamic pivots**) and compute the distances  $\delta(Q, DP_i^Q)$
  - when a lower bound to  $d(Q, O)$  is required, search for available distances  $\delta(Q, DP_i^Q)$  in the D-cache and obtain the  $\max(|\delta(DP_i^Q, O) - \delta(Q, DP_i^Q)|)$ ; that is our tight lower bound distance

# D-cache

- How to choose the dynamic pivots?
  - “Recent” policy
    - simple – we just choose  $k$  previous queries
    - motivation: the recently added distances are likely to still sit in the D-cache
- Data structure: hash table
  - determine individual cell values based on  $id_1, id_2$
  - “Simple” or universal hashing
- Distance insertion
  - Each computed distance is inserted into D-cache
  - Replacement policies
    - obsolete distances (from outdated pivots)
    - distance-based

---

# Snake Table

- D-file works well if
  - distance function is “expensive”
  - problem: overhead (hashing, replacement policy, etc.) is not negligible for “cheap” distances
    - it may avoid many distance computations but the total search time will be large
- Snake Table
  - designed for streams of k-NN queries
  - no preprocessing required
  - query objects fits a “snake distribution”

# Snake Table

- “Snake distribution”
  - consecutive queries are close
  - e.g.: frames from a video shot

---

# Snake Table

- Data structure
  - Table of size  $n \cdot k$ 
    - $n$ : size of the data set
    - $k$ : number of dynamic pivots
  - Dynamic pivots are replaced in round-robin mode
    - each query is a pivot for the next  $k$  queries
    - snake distribution: dynamic pivots are close to next query
- In practice: it performs better than D-file for “cheap” distances

---

# Final remarks

- D-file – an index-free metric access method
  - requires no indexing
  - suitable for online streaming data processing
  - D-cache: a structure used by D-file to cheaply determine lower-bound distances
    - uses distances computed and cached during previous queries processing
- Snake Table
  - lower internal complexity compared with D-cache
  - faster than D-cache when data fit a “snake distribution”

# Búsqueda por similitud

- Búsqueda textual: buscadores Web
  - Ventajas
    - Permite consultas semánticas de alto nivel
    - Fácil de implementar
  - Desventajas
    - Requiere intervención humana
    - Altamente subjetivo
    - Incompleto
-

# Búsqueda por similitud basada en contenido

- Modelo de búsqueda
  - Extracción de características
    - Descriptor (vector)
    - Estructura del descriptor está oculta al usuario
  - Función de similitud
    - Permite comparar descriptores
    - Debe “imitar” la similitud semántica de los objetos

# Búsqueda por similitud basada en contenido

- Tipos de consulta
  - Query-by-example

Consulta por rango

# Búsqueda por similitud basada en contenido

## ■ Espacios métricos

- Función de disimilitud  $\delta$  (distancia), universo  $\mathbf{U}$ , colección  $\mathbf{S} \subset \mathbf{U}$ , objetos  $x, y, z \in \mathbf{U}$
- A mayor  $\delta(x, y)$ , más disímiles son los objetos  $x, y$

## ■ Propiedades topológicas

$\delta(x, y) = 0 \Leftrightarrow x = y$	identity
$\delta(x, y) \geq 0$	non-negativity
$\delta(x, y) = \delta(y, x)$	symmetry
$\delta(x, y) + \delta(y, z) \geq \delta(x, z)$	triangle inequality

## ■ Ventajas de los espacios métricos

- Se conocen muchas métricas
- Postulados apoyan supuestos comunes sobre similitud
- Permite indexamiento y búsqueda eficiente
